

# Installation Guide

## Database Installation

Use MySQL Admin or the command line to import the MySQL Admin Backup script to your desired database. Please remember that the scripts were made using a schema of **codex**. If you want another schema, then please edit the script file to reflect these changes.

Restoring using MySQL Browser will not work. Please use MySQL Admin or the command line.

## Source Code Installation

In order to install CodexWiki you must first read our [requirements guide](#).

1. Place the codex installation anywhere in your webserver. Thanks to ColdFusion 8, CodexWiki uses per-application mappings to where it is placed in the webserver.
2. If you place codex in another location that is not the webroot then you will have to modify the following setting. Open the file **config/coldbox.xml.cfm** and update the **AppMapping** setting to match your location.

```
<-- <I have installed codex under a directory called wiki -->  
<Setting name="AppMapping" value="wiki" />
```

3. By default, CodexWiki uses the datasource called **codex**, which is declared in the transfer *datasource.xml* file. If you would like to change it, then open the file and change the name of the datasource.
4. Make sure that you have [Transfer 1.0](#), [ColdBox 2.6](#) and [ColdSpring 1.2](#) installed.
5. Fire up your browser and hit Codex.
6. The default login/password for the administrator is the following:

username	password
admin	codex

7. (Optional) We have a very simple script to install the verity collection and scheduler. You will find this in **install/install.cfm**. This will only work on Windows/Linux machines as Verity has not been ported to Mac OS X.
